OPENING ARGUMENT

- Although the complexity sciences have done much to advance the social sciences, over the last decade the field has run into some hard situations – thirteen to be exact.
- Some are self-imposed, others come from how 21st century science is conducted.
- Examples include
 - ignoring the wider social sciences
 - privileging computational modelling over qualitative research
 - being tone-deaf about the real world.
- These situations presently prevent the study of social complexity from becoming the disruptive, transdisciplinary field it originally sought to be in the 1990s when the *complexity turn* in the social sciences took place.

OPENING ARGUMENT

- Fortunately, a small but growing global network of scholars are charting new territory.
- **They are part of a fresh turn in complexity, the *social science turn***, which fosters a transdisciplinary, social complexity imagination that, in one way or another, addresses the field's thirteen situations to create new areas of disruptive and highly innovative social inquiry.
- The ***Atlas of social complexity*** charts this new territory, seeking to map its present future.
- Organised around **SIX THEMES**, the Atlas functions as a tour guide, surveying over thirty leading-edge research areas (some still under construction) that readers can variously combine and develop.

OPENING ARGUMENT

- The Atlas is a practical guide for those seeking new ideas and new avenues of study to pursue, all in the hope of fostering the transdisciplinary social complexity imagination needed to address some of the biggest global challenges we, as a world community, presently face.
- **The purpose of this LECTURE is to introduce the Atlas to foster a discussion on the future of the field and for participants to explore what a future map might look like for YOUR WORK in the FIELD OF PSYCHOLOGY.**

OVERVIEW

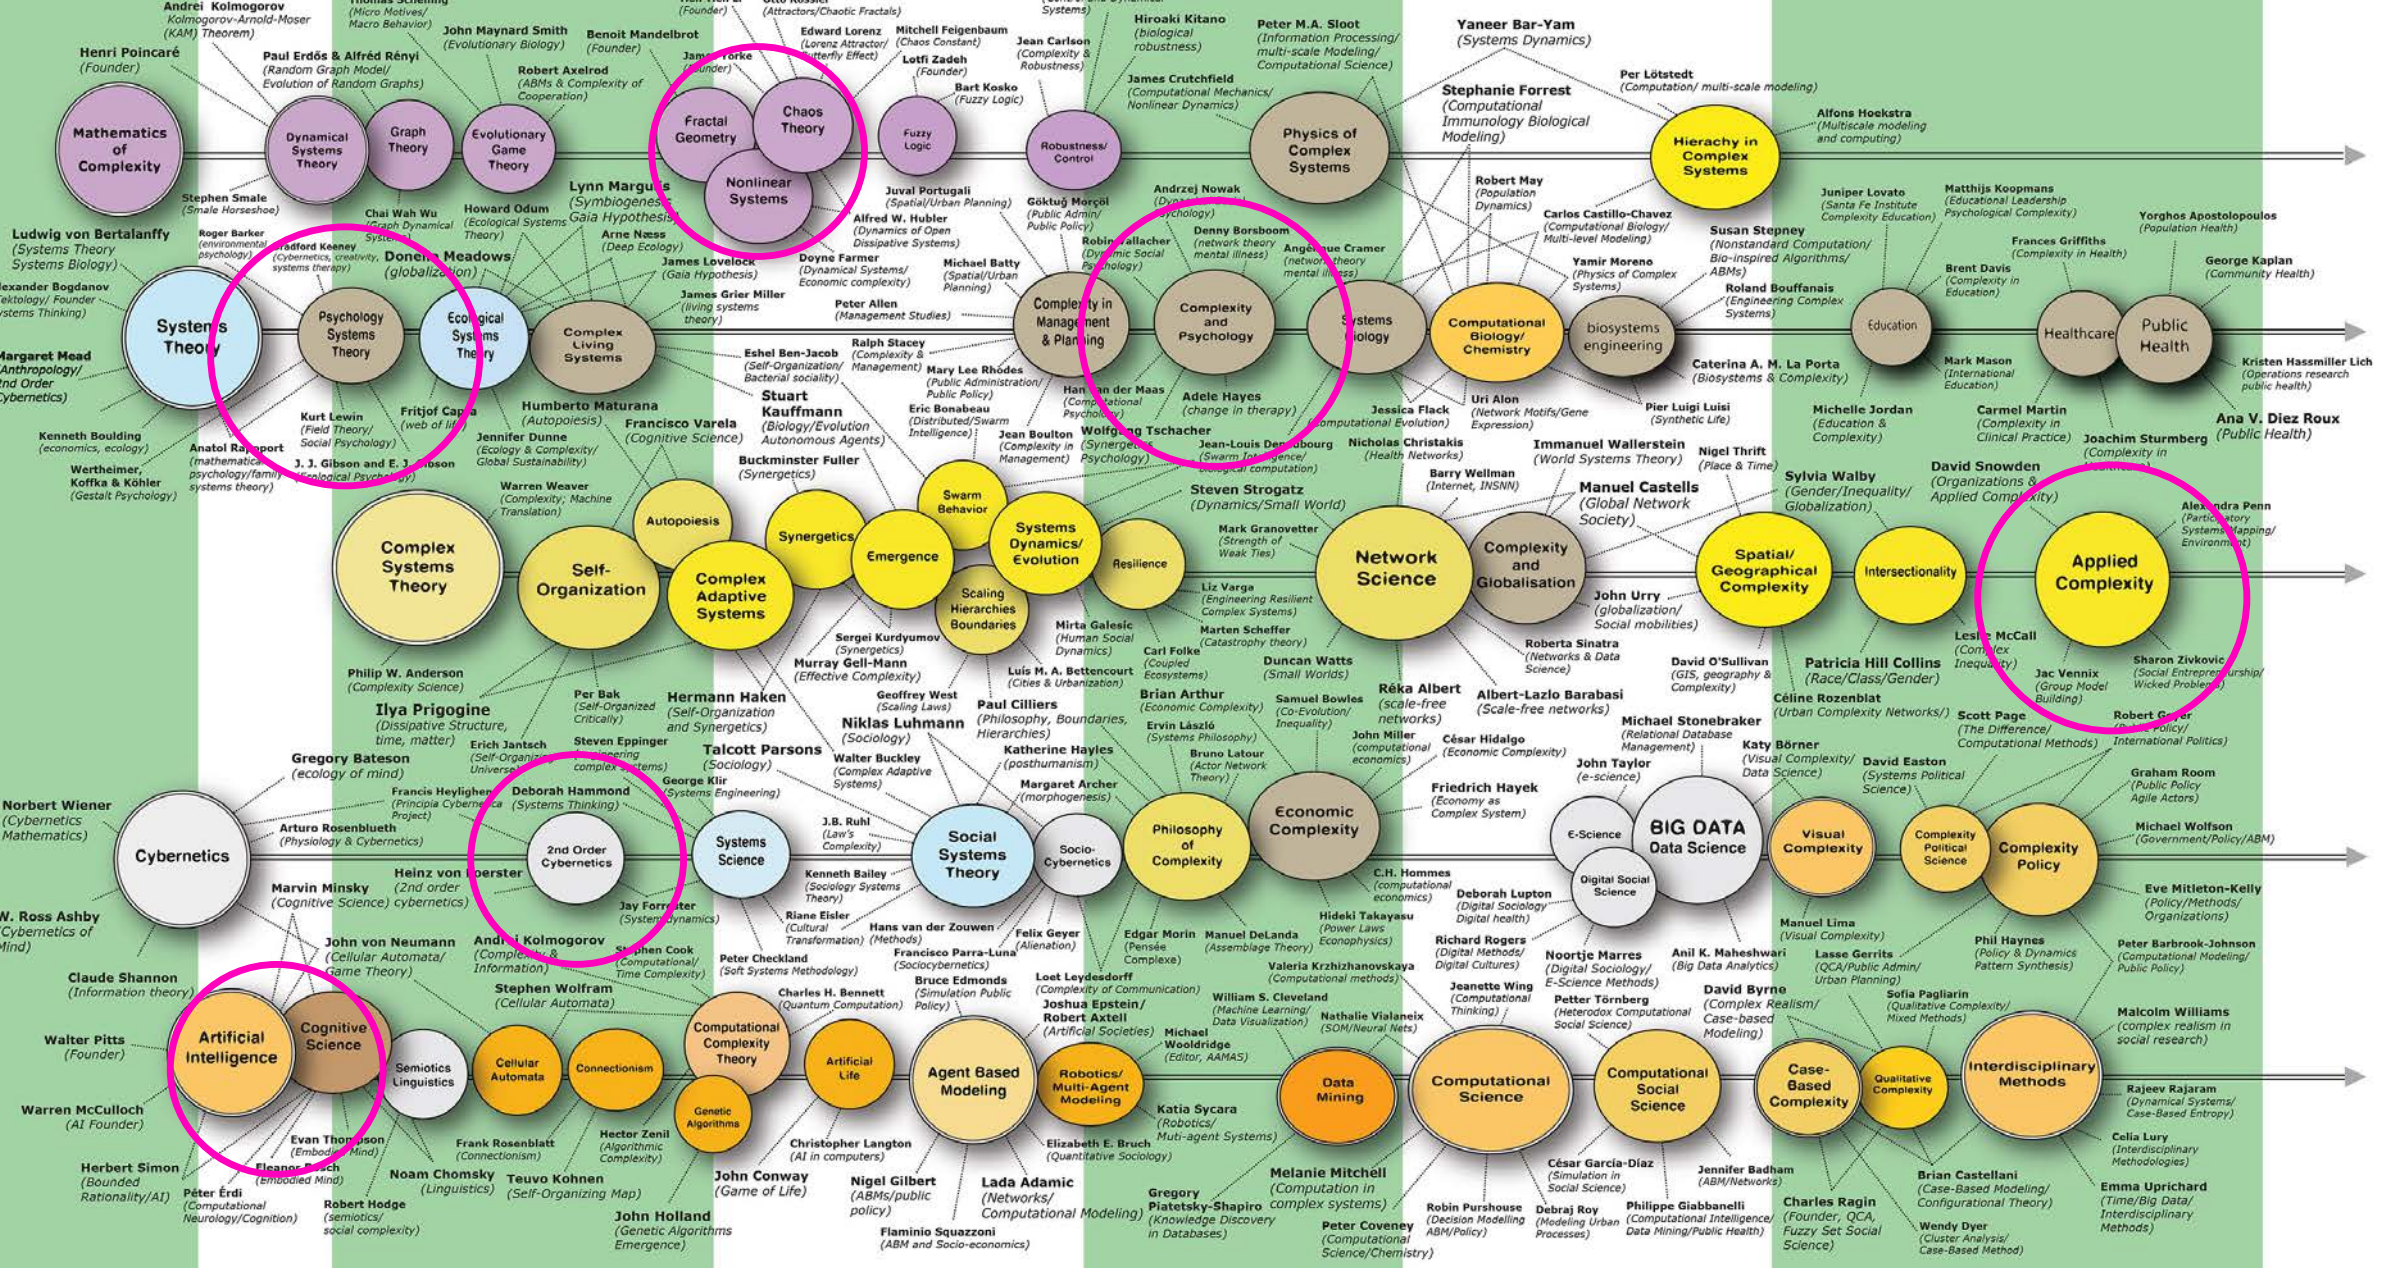

- **Mapping current terrain**
 - Thirteen challenges facing the study of social complexity
- **Charting new territory**
 - The *Atlas of social complexity* charts this new territory, seeking to map its present future.
- **Organised around six major themes:**
 - Setting the context
 - Cognition, emotion and consciousness
 - Dynamics of human psychology
 - Living in social systems
 - Advancing a new methods agenda
 - The unfinished space

A BIT OF HISTORY

1940-1950s 1960's 1970's 1980's 1990's 2000's 2010's 2020's

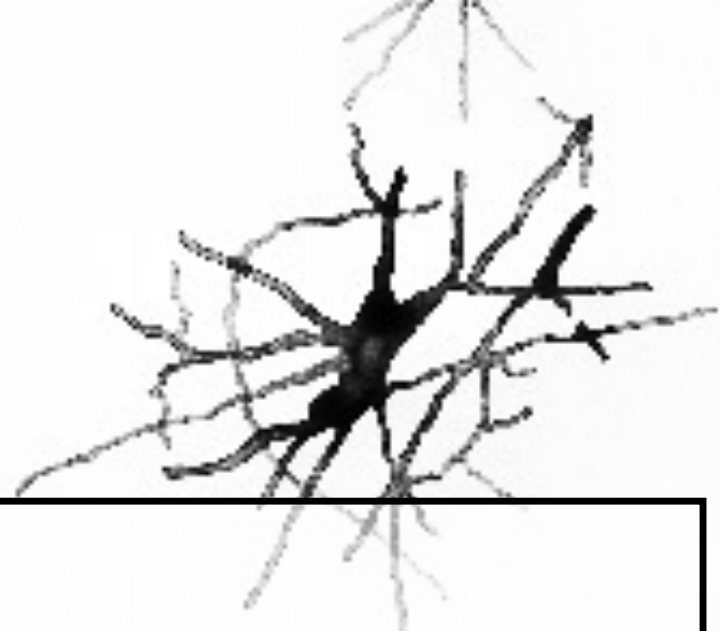

The background is an abstract composition featuring dark, intricate, swirling lines that resemble tangled roots or a complex network. These lines are set against a backdrop of soft, blended colors including shades of blue, purple, yellow, and brown. A central rectangular box with a white border contains the title text.

THE THIRTEEN CHALLENGES

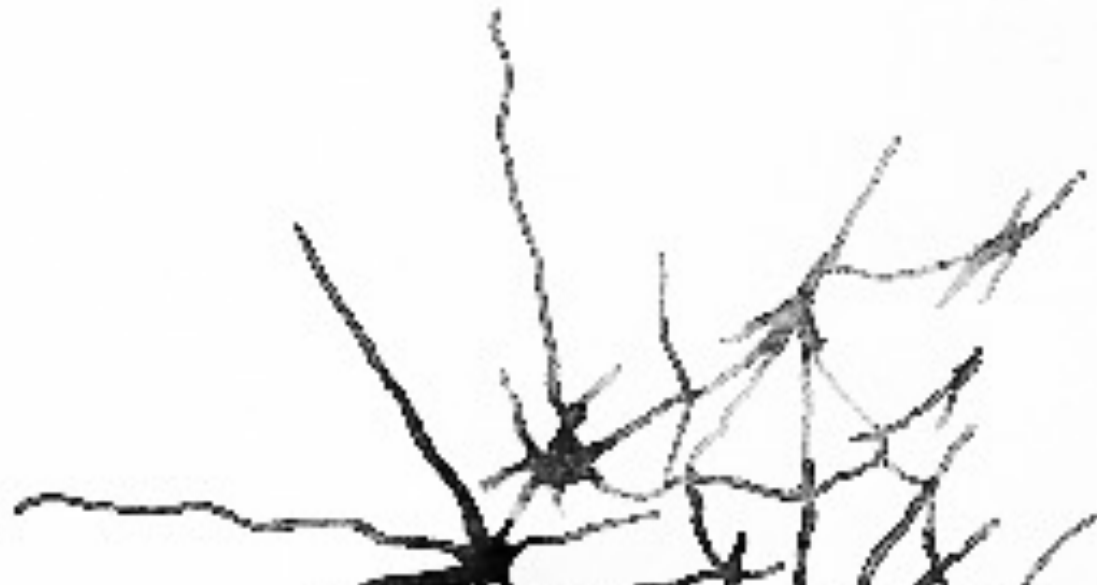

Situation	Characteristics
1. No philosophy of complexity	Few attempts to define an epistemology and ontology for social complexity
2. A failure to engage the wider social sciences	Assumption that the social sciences can be ignored because the complexity sciences would offer superior insights
3. Reinventing the wheel	Reinventing existing insights from the social sciences that are then presented as new insights
4. Old words, new words	Rebranding existing insights using terms from the complexity sciences
5. Obscurantism and mystification	Scientific overreach and complicated jargon combine to suggest that life's biggest questions are uncovered
6. The need for multilevel thinking and modelling	Despite the transdisciplinary approach of social complexity, almost all research focuses on a single level of analysis.
7. Technique in the absence of theory	Focus on computational methods and big data pushes social theory out of sight
8. Learning tools vs. predictive machines	The ability to learn from simulations is replaced by a desire to predict and control social complexity
9. Minor role of qualitative research	Dominance of quantitative research and quantification of data established a blind spot for qualitative data and methods
10. Methodological closing of social scientific mind	Shying away from advances in computational methods sees many social scientists becoming illiterate with such methods
11. The dire sound of technicalities	Going into a spiral of ever-smaller technical refinement while losing the bigger picture out of sight.
12. Being tone-deaf about the real world	Advanced analyses are coupled to crude recommendations that fail to appreciate the complexity in the target domain
13. Practice does not make perfect	Pragmatic and rushed adoption of the complexity sciences by practitioners constitutes verbal detritus

THE SOCIAL COMPLEXITY IMAGINATION

- **BACK TO THE FUTURE**
- In the spirit of C. Wright Mills, the best way for the study of social complexity to overcome its current limitations and to become truly transdisciplinary is to reembrace a **social complexity imagination**.
 - Imagination 1: Moving beyond the traps
 - Imagination 2. Observing the larger universe
 - Imagination 3. Accepting complexity psychologically
 - Imagination 4. Adopting a critical complexity
- This time, however, the inspiration comes from a different direction: it comes from a direct engagement with the social sciences, practice, policy and the arts, in particular those areas that don't associate themselves with the complexity sciences.
- This is part of what we call the **social science turn in complexity**.

Under natural growth conditions, bacteria live in complex hierarchical communities. To conduct complex cooperative behaviors, bacteria utilize sophisticated communication to the extent that their chemical language includes semantic and even pragmatic aspects. I describe how complex colony forms (patterns) emerge through the communication-based interplay between individual bacteria and the colony. Individual cells assume newly co-generated traits and abilities that are not prestored in the genetic information of the cells, that is, not all the information required for efficient responses to all environmental conditions is stored. To solve newly encountered problems, they assess the problem via collective sensing, recall stored information of past experience, and then execute distributed information processing of the 10^9 – 10^{12} bacteria in the colony—transforming the colony into a “super-brain.” I show illuminating examples of swarming intelligence of live bacteria in which they solve optimization problems that are beyond what human beings can solve. This will lead to a discussion about the special nature of bacterial computational principles compared to Turing algorithm computational principles, in particular about the role of distributed information processing.

Autopoiesis and cellular cognition are heavily theoretical and in need for evidence.

Research on bacterial cognition and social behaviours is generating that empirical evidence.

Provides evidence for cellular cognition.

Also leads to new ways of thinking about what constitutes a brain

Shows how lower levels of cognition self-organise, from an evolutionary perspective, to form larger and more complex cognitive systems.

- The founding principal of immunology is the concept of 'identity' and the capacity of immune systems to distinguish between self and non-self.
- Immunity is necessarily a cognitive act and immune systems are broadly cognitive systems.
- Eco-immunology is fundamentally reshaping our understanding of the immune system's complex relationship with its environment and how this relationship can be harnessed to treat disease and infection more effectively.

TO EXPLORE BRAIN- BASED COGNITION, we use a social complexity framework to sort our position relative to six major debates within the field:

- (1) cognition and life,
- (2) the mind/brain dualism
- (3) the unconscious,
- (4) Modularity
- (5) emotions
- (6) brain-based consciousness.

Castellani, Brian and Gerrits, Lasse. Forthcoming 2021

Slides are copyrighted and not for redistribution

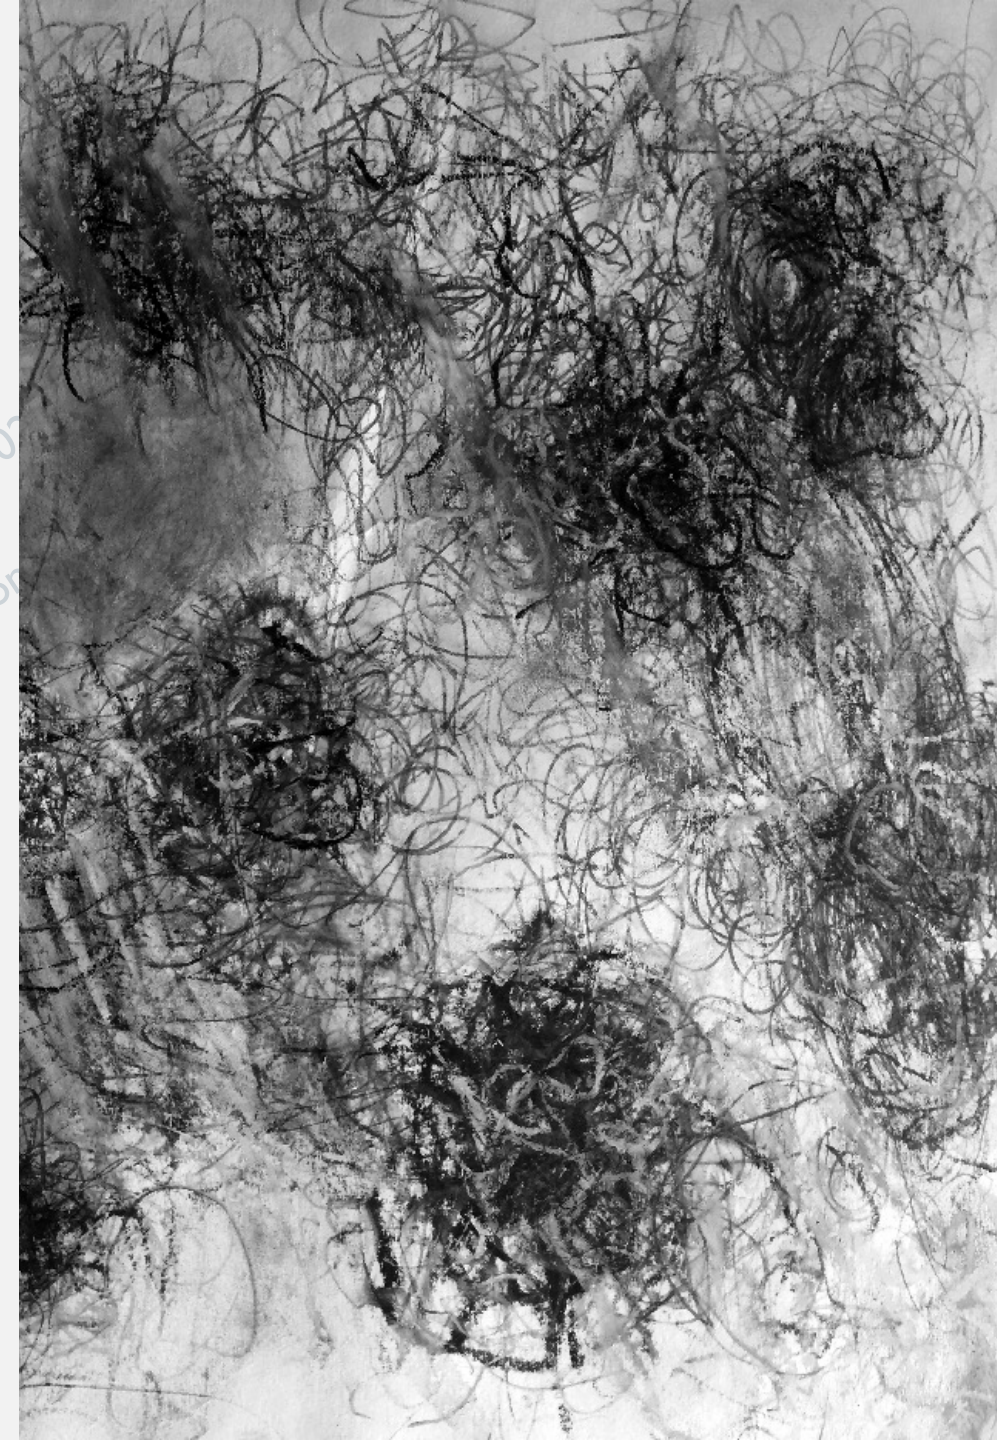

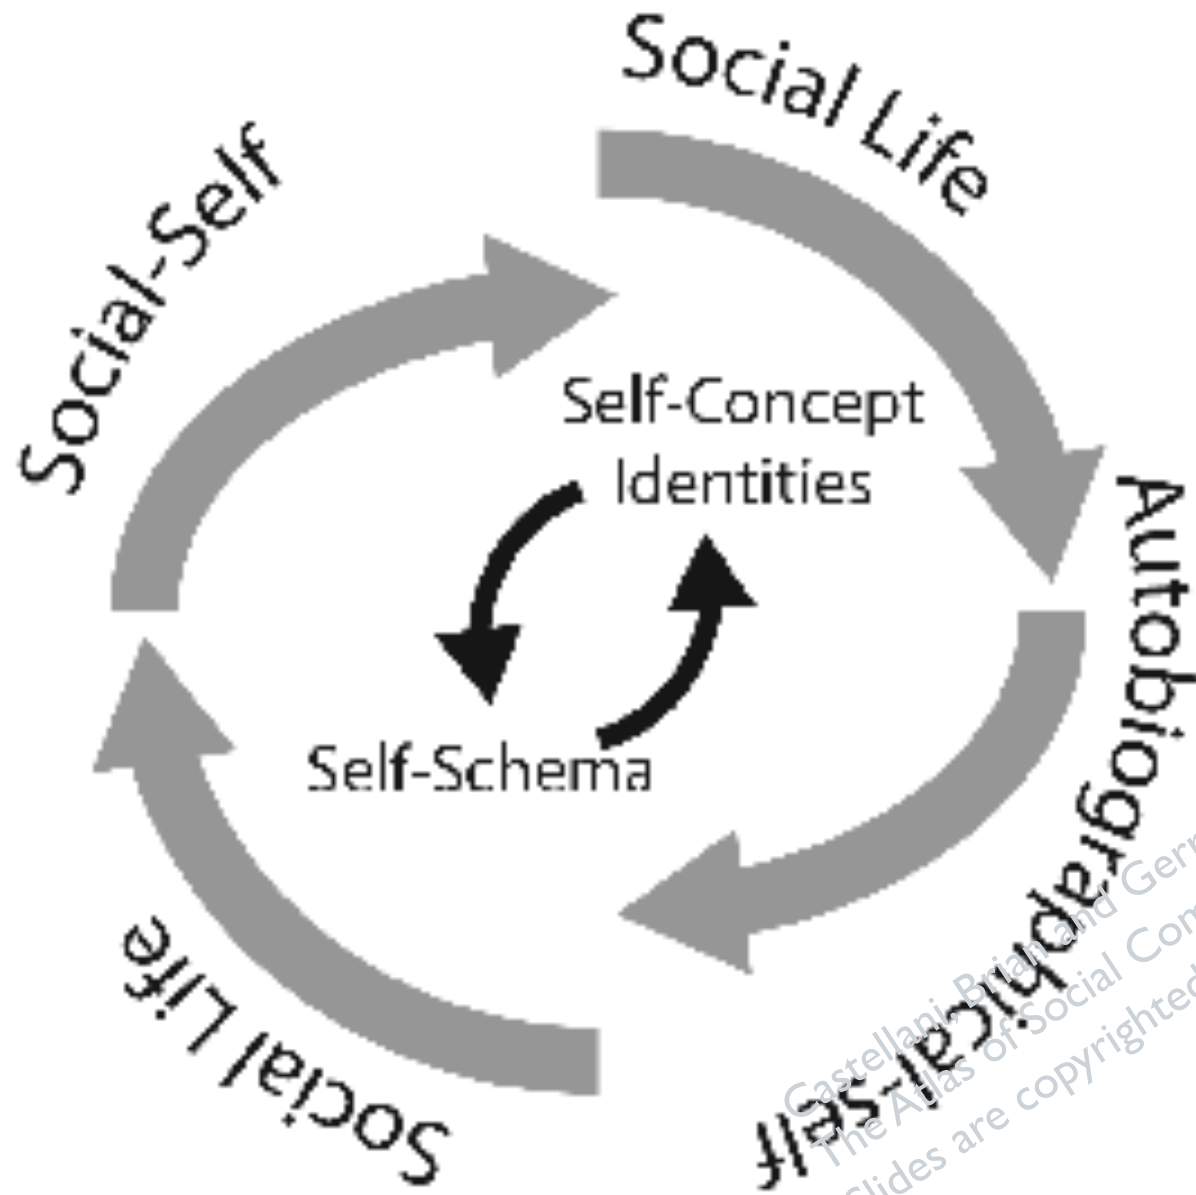

For the first three debates, we use systems thinking and some of its key concepts (namely, structure, organisation and process) to wiggle free of them, hopefully for good.

For the unconscious it means offering a peaceful conceptual divorce that lets both sides go their separate ways.

For emotions, it means redefining brain-based cognition in terms of our paleomammalian past to resolve the Spock Myth that somehow emotions are separate from logic.

With these issues sorted, we move on to outline the beginnings of a new complex systems theory of consciousness,

The Self exists as much for the body as it does for the agency of the self-reflecting mind.

The Self is part of our multi-level, embodied, complex system of consciousness, which can also extend outward to the wider consciousness of the various social groups of which we are a member.

The self also exists for others in our social worlds, including our outward facing *public-self*.

The *embodied-primordial-reflexive* self, if allowed to develop during the lifetime of an individual, and mainly through language acquisition and socialisation, can mature into more complex forms of self, including a higher-level *autobiographical-self* and a *social-self*.

In this way, social groups, socialization, and social context are some of the most powerful evolutionary forces in the development of consciousness for humans and other social animals.

We cannot stress this point enough.

Zusammenfassung

This chapter applies self-organization theory to human resilience and psychotherapy. Three broad classes of modeling are described: network modeling, topological approaches, and time-series analysis. Unique aspects and common features of each model is discussed, and empirical literature is reviewed, with a focus on how these various models contributes to a common theory of biopsychosocial resilience.

Causation and chance: Detection of deterministic and stochastic ingredients in psychotherapy processes

Wolfgang Tschacher & Hermann Haken

Mindfulness, imagination, and creativity

- The human brain is a portal between the physical world and mental life.
- With the brain (as its own form of structure and organisation) acting as a bridge, the two domains, the physical and the mental, are not separate but deeply intertwined, such that life and reality regularly relent to the powers of imagination and creativity, meanwhile the mind is entirely embodied, including the metaphors by which we live.

- Social psychology plays a crucial role as the theoretical and empirical link between the dynamics of human psychology and the macroscopic patterns of social systems.
- As we will explore in this chapter, such distinctions have played themselves out within the complexity sciences and the study of social complexity. The first, which we have yet to introduce, is between a
- psychological versus sociological approach to social psychology.
- the application of complexity science topics to the study of social psychology versus the usage of social psychology to understand life in complex social systems.
- Synchronization.
